

1  
2 RUNNING SAUCY  
3  
4 Both saucy and shatter support the "--help" option for thorough  
5 descriptions of the available arguments to each program.  
6  
7 The general usage is "saucy graphfile". Statistics can be output to  
8 standard error via the "-s" flag.  
9  
10 Saucy does not support multigraphs (graphs with duplicate edges) nor  
11 DIMACS instances that produce multigraphs (CNF instances with duplicate  
12 literals within a clause or, in some cases, duplicate clauses).  
13

#### 14 INPUT FORMAT

15  
16 Saucy uses a simple graph input format. Here is an example:  
17

```
18 5 5 1  
19 0 1  
20 1 2  
21 2 3  
22 3 4  
23 4 0
```

24  
25 This graph represents a 5 vertex circle with all vertices given the same  
26 color; that is, the initial partition of vertices is unit.  
27

28 Whitespace is ignored in the input; newlines can be present anywhere.  
29

```
30 #vertices  
31 #edges  
32 #colors  
33 [#colors-1 split locations]  
34 [#edges vertex pairs]
```

35  
36 Vertices are counted from 0.  
37

38 Here is another example explaining the "split locations" component:  
39

```
40 7 7 2 3  
41 0 1  
42 1 2  
43 2 0  
44 3 4
```

45 4 5

46 5 6

47 6 3

48

49 This represents the graph consisting of a triangle and a square. The  
50 vertices in the triangle  $\{0,1,2\}$  are colored differently than the  
51 vertices in the square  $\{3,4,5,6\}$ , since there are 2 colors, with a split  
52 at vertex 3.

53

54 This is admittedly an awkward way of specifying partitions; the C API is  
55 less awkward.

56

57 OUTPUT FORMAT

58

59 Symmetries are output one per line, as a product of nontrivial orbits.  
60 For the triangle/square graph:

61

62 (3 5)

63 (3 6)(4 5)

64 (0 1)

65 (0 2)

66

67 Each orbit is parenthesized, and the vertices are separated by spaces.

68

69 STATISTICS

70

71 When run with the -s flag, saucy outputs a number of statistics.

72 Here is an example run with the 7pipe benchmark:

73

74 input file = ../graphs/dac/7pipe

75 vertices = 100668

76 edges = 1498971

77 group size = 3.677259e1158

78 levels = 474

79 nodes = 1889

80 generators = 473

81 total support = 119202

82 average support = 252.01

83 nodes per generator = 3.99

84 bad nodes = 0

85 cpu time (s) = 0.22

86

87 group size: the total number of symmetries of the graph. For highly  
88 symmetric graphs this number can be astronomical. Of course saucy does

89 not enumerate this entire set.  
90  
91 levels: the number of recursive decompositions performed by saucy before  
92 it reached a discrete partition. Indicates the maximum search tree  
93 depth.  
94  
95 nodes: number of executions of the partition refinement algorithm. For  
96 saerch nodes, we count refinement twice, since there are two partitions  
97 being manipulated in parallel.  
98  
99 generators: the size of the generating set computed by saucy.  
100  
101 total support: the support of a generator is the number of vertices it  
102 permutes. The total support is the sum of the supports of all  
103 generators.  
104  
105 average support: average number of vertices permuted by a generator.  
106 Indicates the sparsity of the generators found.  
107  
108 nodes per generator: average number of refinements required to find each  
109 generator. Indicates the success of this version of saucy over previous  
110 approaches, whose average would approximate the number of levels.  
111  
112 bad nodes: the number of times the search phase had to backtrack because  
113 of some failed mapping of vertices. Graphs with large amounts of bad  
114 nodes tend to be highly regular graphs, such that degree-based partition  
115 refinement is unable to distinguish vertices very well.  
116  
117 cpu time: the time taken by saucy, in seconds. This does not include  
118 the time required to read the graph into memory.  
119  
120
